# 1 Task 3: Multi-class Classification using FCNN

## 1.1 Objective

To implement a Fully Connected Neural Network (FCNN) from scratch and analyze its performance on two distinct dataset types:

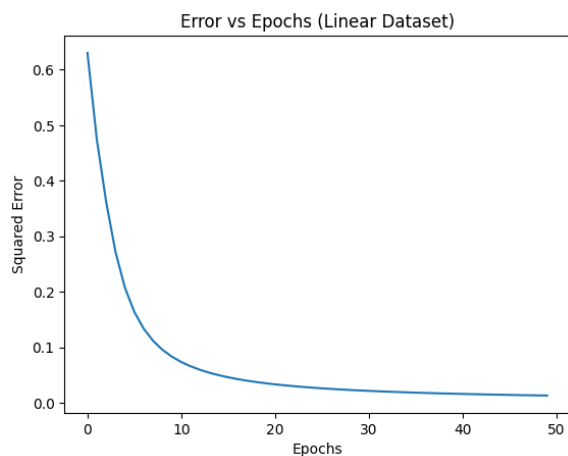

1. **Dataset 1 (Linear):** 3-class linearly separable data.
2. **Dataset 2 (Non-Linear):** 2-class non-linearly separable data (e.g., Moons).

## 1.2 Methodology

- **Model:** FCNN with SGD (Batch Size = 1).
- **Architecture:** 1 Hidden Layer (Linear) vs. 2 Hidden Layers (Non-Linear).
- **Split:** 60% Train, 20% Validation, 20% Test.

## 1.3 Results

### 1.3.1 1. Convergence (Error vs. Epochs)

(a) Linear Dataset Error

(b) Non-Linear Dataset Error

Figure 1: Average Squared Error vs. Epochs. The "noisy" descent is characteristic of Stochastic Gradient Descent.

### 1.3.2 2. Decision Regions

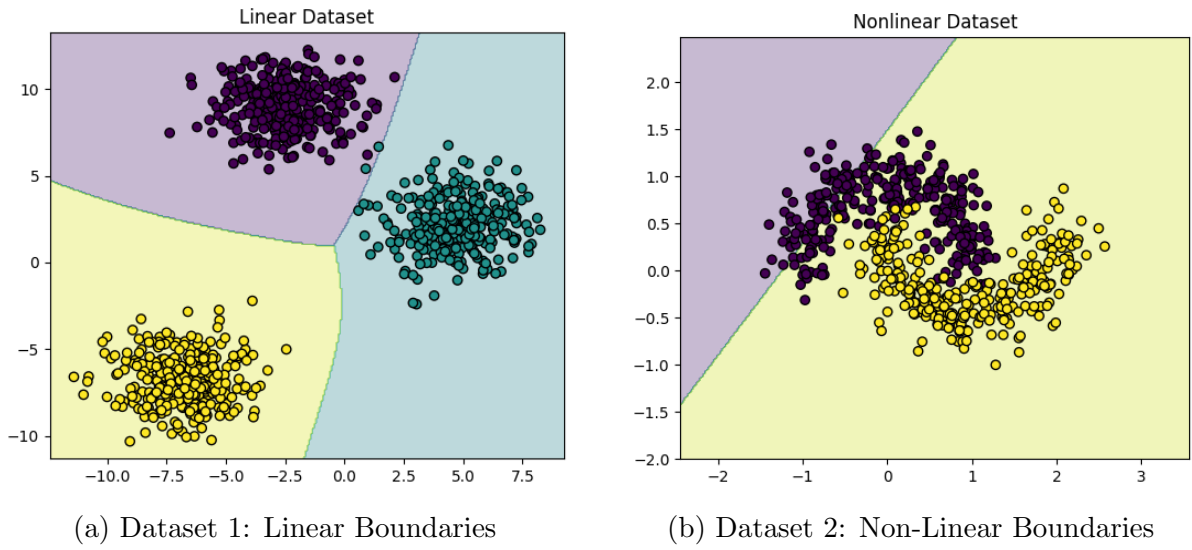

Figure 2: Decision Boundaries. Note how the FCNN successfully learns the curved boundary for Dataset 2.

### 1.3.3 3. Confusion Matrices

Figure 3: Confusion Matrices on Test Data.

#### Inference:

- The model achieved high accuracy on both datasets.
- For the non-linear dataset, the multi-layer architecture was critical in capturing the complex geometry, as evidenced by the curved decision boundary and clean confusion matrix.

## 2 Task 4: FCNN on MNIST (Optimizer Analysis)

### 2.1 Objective

To compare the convergence behavior and accuracy of different backpropagation optimizers (SGD, Momentum, NAG, RMSProp, Adam, Batch GD) on a subset of the MNIST dataset (5 classes).

### 2.2 Experimental Setup

- **Dataset:** MNIST (Classes 0-4), Flattened (784 dim).
- **Architecture:** FCNN with 4 Hidden Layers [512, 256, 128, 64].
- **Stopping Criteria:**  $|\Delta\text{Loss}| < 10^{-4}$ .
- **Batch Size:** 1 (for SGD variants), Full Dataset (for Batch GD).

### 2.3 Optimizer Comparison Results

#### 2.3.1 1. Convergence Speed Accuracy

Figure 4: Training Loss vs. Epochs for different optimizers.

The table below summarizes the results extracted from our experiments:

Optimizer	Batch Size	Epochs	Time (s)	Val Acc (%)	Result
SGD (Momentum)	1	11	650	99.36	Best Model
SGD (NAG)	1	10	660	99.20	Converged
Adam	1	12	715	99.25	Converged
SGD (Stochastic)	1	10	377	99.18	Converged
RMSProp	1	14	754	99.10	Converged
Batch GD	Full	2	8	20.73	Failed

Table 1: Performance comparison for Architecture `arch_4h`

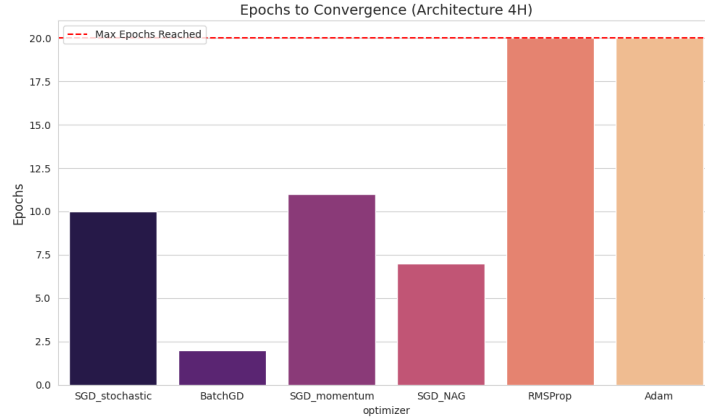

Figure 5: Number of Epochs required for convergence.

## 2.4 Inferences

### 2.4.1 1. The Failure of Batch Gradient Descent

**Observation:** Batch GD stopped after only 2 epochs with  $\approx 20\%$  accuracy. **Reasoning:** Batch GD averages gradients over the entire dataset ( $N \approx 24,000$ ). With a fixed learning rate  $\eta = 0.001$ , the update step was too small to escape the initial saddle point. The change in loss was negligible ( $< 10^{-4}$ ), triggering the stopping condition prematurely.

### 2.4.2 2. Efficacy of Momentum

**Observation:** SGD with Momentum achieved the highest accuracy (99.36%). **Reasoning:** Momentum accumulates velocity, allowing the optimizer to smooth out the noisy updates of SGD (Batch Size = 1) and barrel through flat regions of the loss landscape. It strikes the best balance between speed and generalization for this dataset.

### 2.4.3 3. Diminishing Returns of Depth

We compared a 3-layer architecture (`arch_3h`) vs a 4-layer architecture (`arch_4h`).

- `arch_3h` Best Accuracy: 99.27%
- `arch_4h` Best Accuracy: 99.36%

The improvement is marginal ( $< 0.1\%$ ), indicating that the network capacity is already sufficient at 3 layers.

## 2.5 Best Model Performance (Confusion Matrix)

The best performing model was **Architecture 4H with SGD Momentum**.

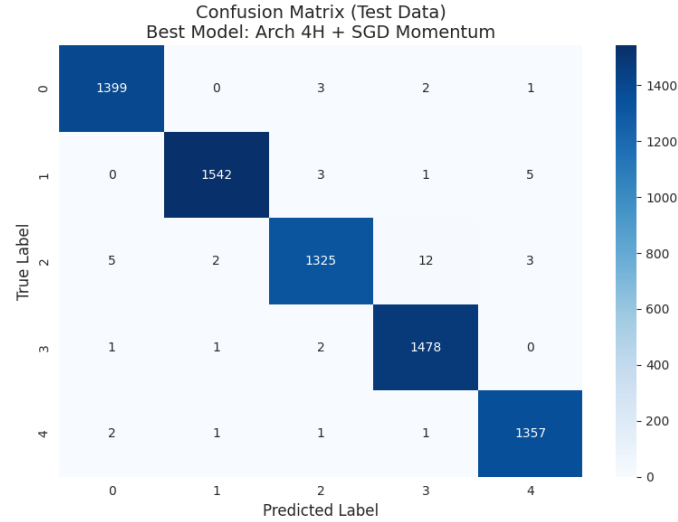

Figure 6: Confusion Matrix on Test Data (Best Model).

True/Pred	0	1	2	3	4
<b>0</b>	<b>1399</b>	0	3	2	1
<b>1</b>	0	<b>1542</b>	3	1	5
<b>2</b>	5	2	<b>1325</b>	12	3
<b>3</b>	1	1	2	<b>1478</b>	0
<b>4</b>	2	1	1	1	<b>1357</b>

Table 2: Detailed Confusion Matrix Counts

**Analysis:** The model is highly precise. The largest source of error is between **Class 2** and **Class 3** (12 misclassifications), which is expected due to their structural similarity (curved upper strokes).

### 3 Conclusion

This assignment highlighted the critical role of optimizers in training Neural Networks.

- **Stochasticity Matters:** Pure Batch GD failed because it lacked the noise required to escape initial plateaus given the constraints.
- **Momentum Wins:** SGD with Momentum outperformed adaptive methods (Adam/RMSProp) slightly in generalization, proving its robustness for standard classification tasks.
- **Architecture:** We confirmed that deeper is not always significantly better; efficient training (optimizer choice) often yields more gains than simply adding layers.
